

Apparently it is going to be possible on the average to put upwards of 6 ounces a day into each of these birds, of which better than 2 ounces will be dry mash. In addition, the birds are consuming some pellets, but the quantity of these per day has not yet been determined. This experiment is being continued checking weights, gains, and feed consumption regularly, and a more detailed report will be submitted at the conclusion of the experiment. It seems logical that this amount of force feeding should produce more rapid weight gains in the experimental group, but whether such will be the case remains to be seen.
